

New perspectives – revenue and cost optimized pumped storage concepts

Dr. Klaus Engels
Louisville, KY – July 19, 2012

Future system demands require highly flexible PSP with optimized revenues and cost structures

- Currently, pumped storage plants (PSPs) are the only mature large scale option to store energy and react flexible on system demand.
- Considering all revenue streams – wholesale market, ancillary services and portfolio effect – PSPs are profitable, even in tough market environment.
- The remaining optimization lever is cost of a PSP – beside other positions, the machine set is a main cost driver, which can be optimized.
- To display the value contribution of a PSP – technically and economically - the optimal dispatch needs to be simulated with modern tools.
- As the plant flexibility becomes more important, the majority of the revenues come from the ancillary services (secondary reserve).
- Thus, the optimal machine concept is highly flexible at minimal costs and has the right size in the market portfolio.

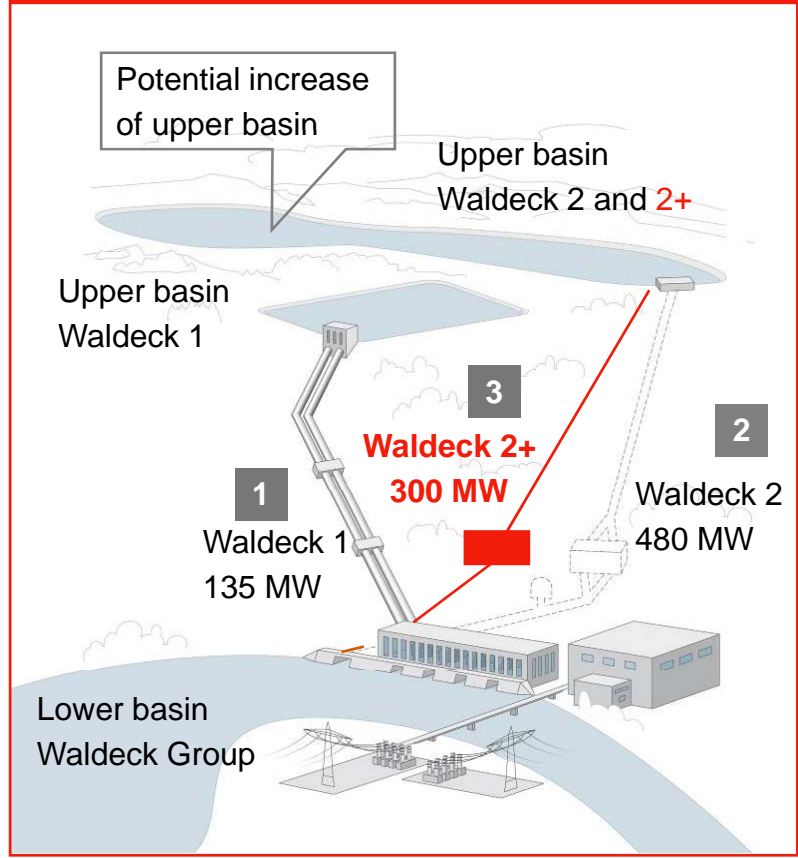

E.ON's Waldeck 2+ project is an extension of the existing interconnected Waldeck Group

European hydro power portfolio

No. of operated hydro plants	212
Efficient capacity	6.161 MW
Annual net generation	18,5 TWh

The Waldeck Group in central Germany

Demand for flexibility will permanently increase within the next years due to growing share of renewables feed-in

Annual residual load

Decrease of residual load

Relative frequency of load changes of annual residual load

Increase of fluctuation

Energy production* [TWh]

*) Germany/ input for simulation without export, direct industry, railway or auxiliary consumption

Profitability of PSP is supported by high demand of ancillary services – increasing revenue share accordingly

2009 to 2011

Revenue distribution

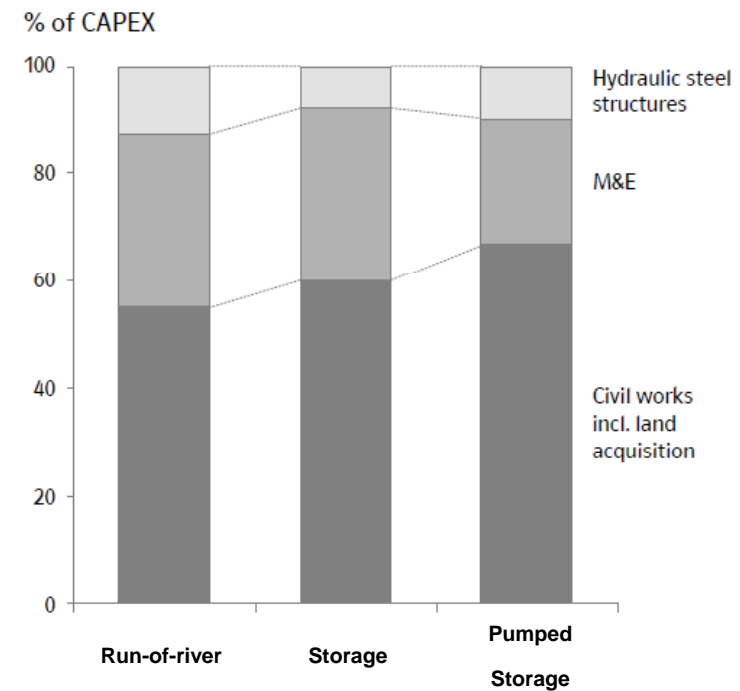

Typical investment cost structure for new build projects of hydropower plants incl. pumped storage plants

Basic CAPEX set

		Plant type - driver for revenues		
		Run-of-river	Storage	Pumped storage
Head - driver for CAPEX	High Head >150m	1,400–2,800	1,850–4,600	700–3,200
	Medium Head 50–150m	1,600–3,400	2,100–4,800	
	Low Head <50m	1,900–3,800		

CAPEX (€/kW)

Split of CAPEX

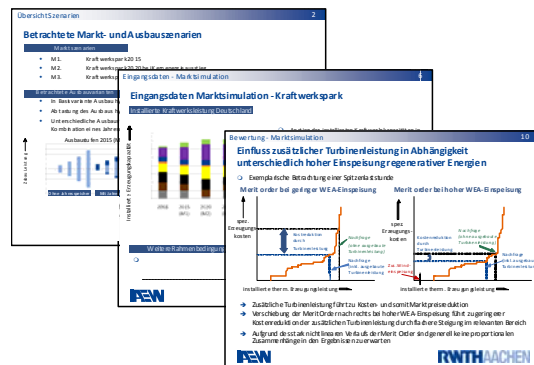

General note: depending on the real project, individual cost structure may be different!

To optimize the technical concept a comprehensive three-step evaluation approach has been applied

New Build Potential

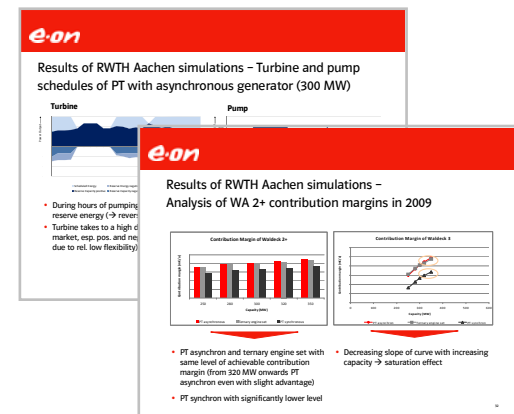

How much additional pumped-storage capacity fits into the German market?

Extension Stage

What is the market optimal capacity and upper basin size?

Machine Concept

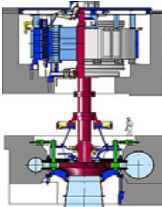

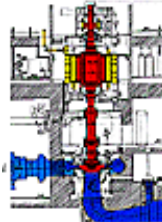

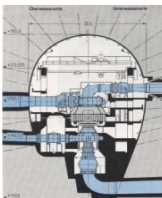

How much flexibility is required in today's market? → Which machine type should be applied?

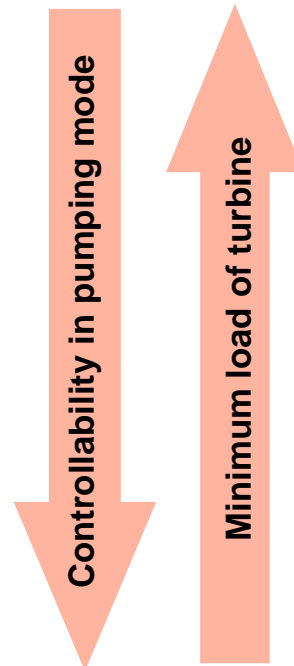

Machine types differ in their flexibility to participate in the reserve markets and in their investment cost

Three technical alternatives are available:

- 1** Pumped turbine with synchronous generator 
- 2** Pumped turbine with asynchronous generator 
- 3** Ternary machine set 

Two main flexibility parameters of given machine types were simulated:

- 1** Limited flexibility (no controllability of pump, high min. load of turbine)
- 2** Medium flexibility (variation of power output of pump possible, medium min. load of turbine)
- 3** Maximum flexibility (hydraulic short circuit can be applied, low min. load of turbine)

Investments required:

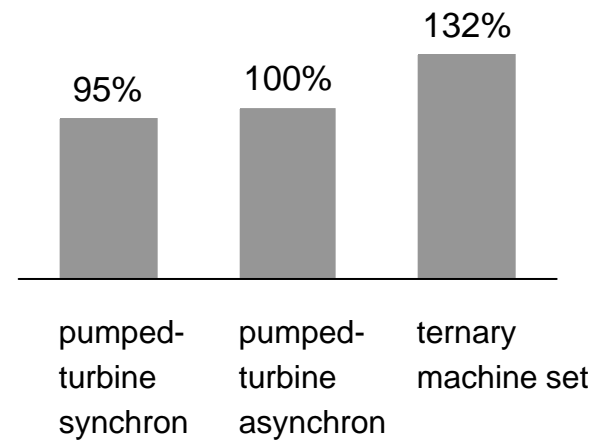

An asynchronous pump-turbine is proposed as optimal machine concept – dependent on the individual situation

Simulated contribution margins:

Capital expenditure assumptions *:

Asynchron pumped-turbine and ternary machine set reach same level of contribution margin, whereas synchron pumped-turbine remains 20% behind.

Cost-benefit-analysis with consideration of capital expenditure reveals pumped-turbine with asynchronous generator to be the most beneficial solution.

Curriculum Vitae

- University Degree in **Electrical Engineering**,
RWTH Aachen University, Germany
- University Degree in **Economics**,
FernUni Hagen, Germany
- 1997 – 2002 Academic assistant and **PHD studies** at
RWTH Aachen University
- 2002 – 2004 **Asset Manager Transmission Grid**
RWE Energy AG, Dortmund
- 2005 – 2008 **Project Manager**
Roland Berger Strategy Consultants,
Dusseldorf/Munich
- 2008 – 2010 **Head of Business Development**
E.ON Wasserkraft, Landshut
- since 2010 **Vice President Asset Risk and
Governance Hydro**, E.ON Fleet
Management Generation
- Recently invited to **Advisory Working Group for the study
“Modeling and Analysis of Value of Advanced Pumped
Storage Hydropower in the U.S.”** of DoE

The energy-economic modeling of pumped-storage plants must address both wholesale and reserve markets

Wholesale & reserve market

Markets for scheduled energy

- Spot- and Future market
 - Purchase and Sale of electrical energy
 - Spot market: hourly products
 - Future market: variable product definitions
 - Modelling by price-demand-function, aggregated for total market

Reserve Markets (II)

- Criteria for award of offer/contract: Only merit-order of capacity price
- Modelling of capacity-price-demand-function
- Criteria for calling of reserve energy: merit-order of energy price
- Modelling of reserve energy calling by energy price dependent calling probability (time row)
- Bilateral reserve contracts (e.g. hourly reserve)
 - Purchase and offer
 - Possibly long-term contracts
 - Design not standardized
 - Modelling as fixed amount of reserve capacity

IAEW RWTH AACHEN

Particularities for scheduled energy and reserve markets (prices, sellable reserve capacities, calling signals...)

Thermal & hydraulic systems

Hydraulic generation

- Time variable natural inflows
- Minimum and maximal discharge of pumps, turbines, penstocks etc.
- Starting and end volume for each reservoir
- Revisions and forced commitments
- Provision of scheduled energy and reserve capacity
- Load dependent efficiency...

Reserve provision by hydraulic power plants

- Pumped-storage plant participation in scheduled energy and positive minute reserve market

reserve energy availability, e.g.
 $100 \text{ MW} \cdot 4 \text{ h} = 400 \text{ MWh}$

max. generation limit, e.g. elec.energy: 80 MW, reserve: 100 MW

reserve: consideration of requested reserve energy, e.g. with calling probability
 $P_{FA} = 0.2$
 $0.2 \cdot 100 \text{ MW} \cdot 1 \text{ h} = 20 \text{ MWh}$
 elec.energy: 80 MW · 1 h = 80 MWh

IAEW RWTH AACHEN

Hydraulic constraints and technical restrictions in the considered system (incl. thermal plants → portfolio approach)

Evaluation method

Methodology

Two-stage method as mixed whole-number quadratic problem for power generation and trading planning

- Objective: Determination of the maximum contribution margin of a generation pool consisting of thermal and hydro power plants under consideration of spot and reserve markets

IAEW RWTH AACHEN

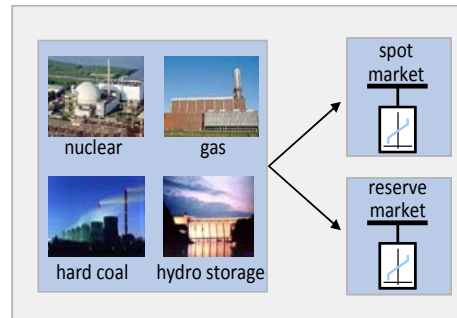

- An **integrated algorithm** optimizes the power plant scheduling on wholesale and reserve market
- Results:** optimized **dispatch** of portfolio and **contribution margin** of PSP (incl. portfolio effect)

Additional restrictions needed to be defined in simulation model to reflect machine type characteristics

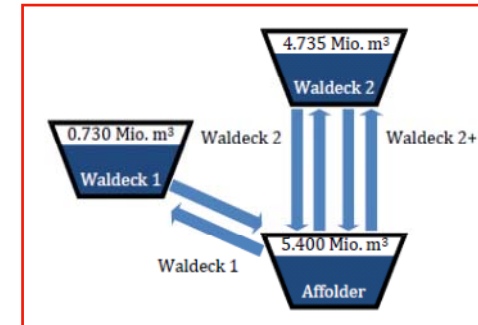

$$\begin{aligned}
 & B_{SP,m}^i = 0, \text{ else } B_{SP,m}^i = 1 \\
 & B_{ST,m}^i = 0, \text{ else } B_{ST,m}^i = 1 \\
 & B_{ST,m}^i \left(E_{SE}^i + \sum_{j=1}^n P_{Res,j}^i + \sum_{j=1}^n E_{Res,j}^i - SC_{max,pos} = 0 \right) \\
 & E_{SE}^i - \sum_{k=1}^m P_{Res,j}^i - \sum_{k=1}^m E_{Res,j}^i - SC_{max,neg} = 0
 \end{aligned}$$

- With re-definition of optimization problem complexity increased tremendously
- **Simulation approach needed to be split into two steps** to limit calculation times

Step 1:

Portfolio-simulation without restrictions in order to conclude how much reserve capacity is provided by Waldeck Group if part of the portfolio.

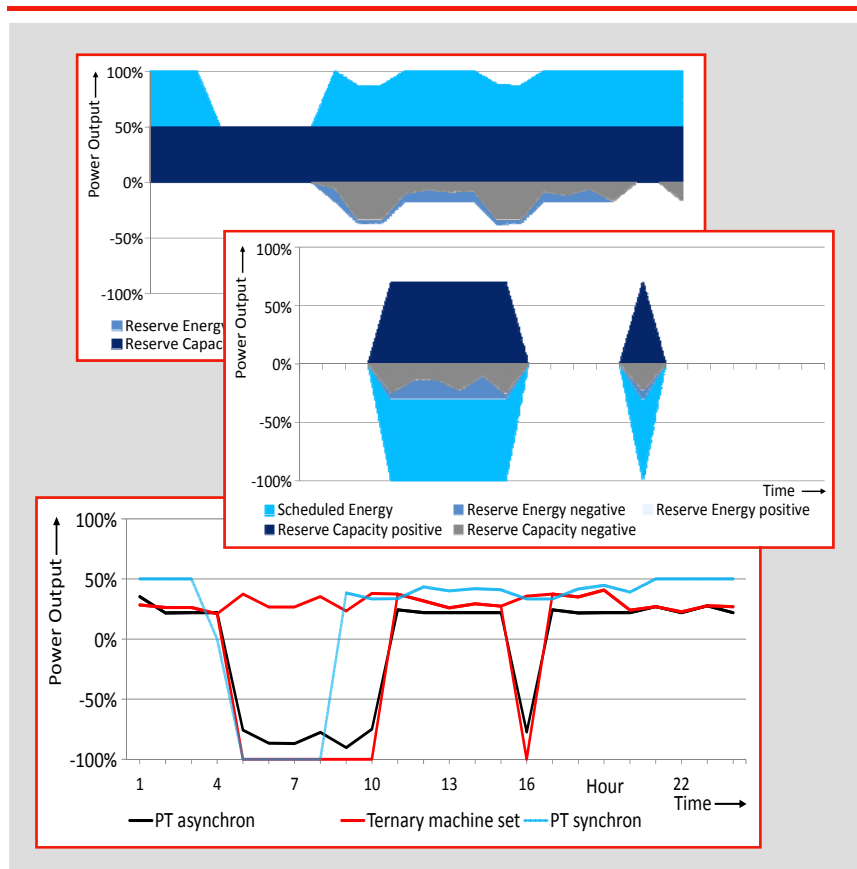

Step 2:

Machine type simulation on stand-alone basis for Waldeck-Group with portfolio-simulated reserve capacity provision as input and 2009 actual prices

Waldeck 2+ extracted from group results

Analysis of run-of-day schedules showed that machine type specifics were captured well in simulation

Exemplary 24-h-schedules

Take-aways

- **No full load operation in wholesale market**, irrespective of machine type
- Large amount of **capacity sold to reserve market**
- Increasing **flexibility of machine types fosters reserve market participation**
- **Hardly any standstill times** to be able to participate in PCR market, which is very lucrative in Germany
- Simulated energy output schedule looks **different from a traditional PSP schedule of today**
